A proper *q*-coloring of H = (V, E) is a map $\phi : V \rightarrow [k]$ such that no edge is monochromatic.

The chromatic number $\chi(H)$ is the minimum value q such that H has a proper q-coloring.

A hypergraph *H* is simple if $|e \cap f| \le 1$ for all $e, f \in E$.

The random hypergraphs $H_{n,m;k}$ (resp. $H_{n,p;k}$) have vertex set [*n*] and *m* random edges from $\binom{V}{k}$ (resp. each edge in $\binom{V}{k}$ is included with probability *p*).

イロト 不得 とくほ とくほ とうほ

The chromatic number of random hypergraphs

The case of random graphs, k = 2, has been well-researched. For $k \ge 3$ we have

Theorem (Dyer, Frieze, Greenhill (2015))

Define $u_{k,q} = q^{k-1} \ln q$ for integers $k \ge 2$ and $q \ge 1$. Suppose that $k \ge 2$, $q \ge 1$, and let *c* be a positive constant. Then for $H = H_{n,cn;k}$,

• If $c \ge u_{k,q}$ then w.h.p. $\chi(H) > q$.

If k ≥ 2 and max{k, q} ≥ 3 then there exists a constant c_{k,q} ∈ (u_{k,q-1}, u_{k,q}) such that if c < c_{k,q} is a positive constant then w.h.p. χ(H) ≤ q.

In particular this generalises an earlier result of Achlioptas and Naor [2005].

In particular this generalises an earlier result of Achlioptas and Naor [2005].

The theorem was later sharpened by Ayre, Coja-Oghlan and Greenhill [2018].

イロト 不得 とくほ とくほ とうほ

Given a graph *G* and $q \ge \chi(G)$, there is the problem of generating a (near) random proper coloring of *G*.

Given a graph *G* and $q \ge \chi(G)$, there is the problem of generating a (near) random proper coloring of *G*.

The first result in this area is due to Jerrum (1995) who showed that an MCMC approach works for $q \ge 2\Delta(G)$.

Given a graph *G* and $q \ge \chi(G)$, there is the problem of generating a (near) random proper coloring of *G*.

The first result in this area is due to Jerrum (1995) who showed that an MCMC approach works for $q \ge 2\Delta(G)$.

This was improved to $q \ge 1.76\Delta$ by Vigoda (2000).

We discuss using Glauber Dynamics to randomly color an arbitrary simple hypergraph.

・ロト ・ 同ト ・ ヨト ・ ヨト … ヨ

We discuss using Glauber Dynamics to randomly color an arbitrary simple hypergraph.

Frieze and Melsted (2011) gave examples of blocked colorings:

Theorem

Let $k \geq 3$ and let m, q be sufficiently large. Suppose that $\epsilon \leq \frac{1}{10k!}$. Then there exists a hypergraph H with qm vertices and maximum degree $\Delta \in [\frac{\epsilon qm}{2(k-1)!}, \frac{2\epsilon qm}{(k-1)!}]$ and a coloring with q colors so that there are no Glauber moves.

イロト 不得 とくほ とくほ とうほ

So, for small q we have to be satisfied with generating a (near) random coloring from a giant component of Γ .

イロト 不得 とくほ とくほ とうほ

Theorem

Let H be a k-uniform simple hypergraph with maximum degree Δ where $k \geq 3$. Suppose that

$$2\Delta \geq q \geq \max\left\{C_k \log n, 10k\epsilon_k^{-1}\Delta^{1/(k-1)}\right\}$$

Suppose that the initial coloring X_0 is chosen randomly from q^V . Then for an arbitrary constant $\delta > 0$ we have

 $d_{TV}(X_t, Y) \leq \delta$

for $t \geq t_{\delta}$, where $t_{\delta} = 2n \log(2n/\delta)$.

Let *X* be a coloring of *V*. For a vertex $v \in V$ and $1 \le i \le k - 1$

 $E_{v,i,X} = \{e: v \in e \text{ and } | \{X(w): w \in e \setminus \{v\}\} | = i\}$

be the set of edges *e* containing *v* in which $e \setminus \{v\}$ uses exactly *i* distinct colors under *X*.

Let *X* be a coloring of *V*. For a vertex $v \in V$ and $1 \le i \le k - 1$ $E_{v,i,X} = \{e : v \in e \text{ and } | \{X(w) : w \in e \setminus \{v\}\} | = i\}$ be the set of edges *e* containing *v* in which $e \setminus \{v\}$ uses exactly *i* distinct colors under *X*.

Let $y_{v,i,X} = |E_{v,i,X}|$, so that the number of bad colors for v is given by $|B(v, X)| = y_{v,1,X}$ for all v, X.

We define the sequence $\epsilon = \epsilon_k, \epsilon_k^2, \ldots, \epsilon_k^{k-2}$.

Definition

We say that X is ϵ -bad if $\exists v \in V, 1 \leq i \leq k - 2$ such that

 $y_{v,i,X} \ge \mu_i$ where $\mu_i = (\epsilon_k q)^i$.

Otherwise we say that X is ϵ -good.

We start the chain X_t with a random q-coloring from q^V and then couple it against a random proper coloring Y_t .

We start the chain X_t with a random *q*-coloring from q^V and then couple it against a random proper coloring Y_t .

If we know that both X_t , Y_t are ϵ -good then we can show in a straightforward manner that their Hamming distance decreases in expectation in a single iteration.

We start the chain X_t with a random *q*-coloring from q^V and then couple it against a random proper coloring Y_t .

If we know that both X_t , Y_t are ϵ -good then we can show in a straightforward manner that their Hamming distance decreases in expectation in a single iteration.

To show that a random proper coloring is ϵ -good w.h.p. we use the local lemma in the following way.

▲御♪ ▲臣♪ ▲臣♪ 二臣

Let \mathbf{Pr}_{Ω} refer to uniform probability on q^{V} and let \mathbf{Pr}_{Q} refer to uniform probability on proper colorings.

It follows from Haeupler, Saha and Srinivasan (2011) that

$$\mathsf{Pr}_{\mathcal{Q}}(\mathcal{A}_{\mathcal{V}}) \leq \mathsf{Pr}_{\Omega}(\mathcal{A}_{\mathcal{V}}) \prod_{f \in \mathcal{N}_{\mathcal{V}}} (1 - x_f)^{-1},$$

where $\mathcal{N}_{v} = \{ f : f \cap e \neq \emptyset \text{ and } f \cap e \text{ for some } e \ni v \}.$

The proof of HSS is a straightforward adaptation of the usual Local Lemma proof.

The proof of HSS is a straightforward adaptation of the usual Local Lemma proof.

For our given q, $\Pr_{\Omega}(\mathcal{A}_{v})$ is small and then so is $\Pr_{\mathcal{Q}}(\mathcal{A}_{v})$.

Open Questions

• Does Glauber Dynamics succeed in polynomial time on random Hypergraphs with $q = O(n^{1/(k-1)})$ colors?

◆□▶ ◆□▶ ★ □▶ ★ □▶ → □ → の Q ()

- Does Glauber Dynamics succeed in polynomial time on random Hypergraphs with $q = O(n^{1/(k-1)})$ colors?
- **2** Remove the $\Omega(\log n)$ requirement for coloring arbitrary simple hypergraphs.

Guo, Liao, Lu and Zhang (2018) deals with deterministically, approximately, counting colorings. The requirements are

 $k \geq 28, q \geq 315\Delta^{14/(k-14)}$.
