### ANOVA and Statistical Models

R. A. Bailey School of Mathematical Sciences

r.a.bailey@qmul.ac.uk

ESD, Queen Mary, University of London, 3 February 2010

### Outline

- 1. Comparing three or more conditions
- 2. Models with submodels
- 3. More complicated families of models

### An experiment on dairy cows

An experiment to compare the effects of three different diets on milk production used 11 Holstein dairy cows at similar points in their lactation cycles. They were fed the diets for three weeks. During the third week, the average daily milk production was recorded for each cow, in pounds per day.

Do the diets have different effects on milk yield?

## Assumptions and vocabulary

Assumption: yield depends on diet.

Model:

yield on cow 
$$i = \begin{cases} K_A + \varepsilon_i & \text{if on diet A} \\ K_B + \varepsilon_i & \text{if on diet B} \\ K_C + \varepsilon_i & \text{if on diet C} \end{cases}$$

where  $\varepsilon_1, \ldots, \varepsilon_{11}$  are independent (normal) random variables with mean zero and variance  $\sigma^2$ .

## Assumptions and vocabulary

Assumption: yield depends on diet.

Model:

yield on cow 
$$i = \begin{cases} K_A + \varepsilon_i & \text{if on diet A} \\ K_B + \varepsilon_i & \text{if on diet B} \\ K_C + \varepsilon_i & \text{if on diet C} \end{cases}$$

where  $\varepsilon_1, \ldots, \varepsilon_{11}$  are independent (normal) random variables with mean zero and variance  $\sigma^2$ .

Estimate  $K_A$  as the average yield of cows on diet A (and similarly for the other diets).

This gives the fit (of the model) for each cow.

## Assumptions and vocabulary

Assumption: yield depends on diet.

Model:

yield on cow 
$$i = \begin{cases} K_A + \varepsilon_i & \text{if on diet A} \\ K_B + \varepsilon_i & \text{if on diet B} \\ K_C + \varepsilon_i & \text{if on diet C} \end{cases}$$

where  $\varepsilon_1, \ldots, \varepsilon_{11}$  are independent (normal) random variables with mean zero and variance  $\sigma^2$ .

Estimate  $K_A$  as the average yield of cows on diet A (and similarly for the other diets).

This gives the fit (of the model) for each cow.

data = fit + residual.

## Data for milk experiment

Diet	Yield	Diet mean				
	Data	Fit	Residual	Data <sup>2</sup>	Fit <sup>2</sup>	Residual <sup>2</sup>

## Sums of squares: I

Pythagoras' Theorem (in 11 dimensions) shows that

sum of the squares of data = sum of squares of fits + sum of squares of residuals

## Sums of squares: I

Pythagoras' Theorem (in 11 dimensions) shows that

```
sum of the squares of data = sum of squares of fits + sum of squares of residuals
```

```
sum of the squares of fits =  (\text{mean for diet A})^2 \times \text{number of cows on diet A}  + (\text{mean for diet B})^2 \times \text{number of cows on diet B}  + (\text{mean for diet C})^2 \times \text{number of cows on diet C}
```

## Sums of squares: I

Pythagoras' Theorem (in 11 dimensions) shows that

sum of the squares of data = sum of squares of fits + sum of squares of residuals

sum of the squares of fits =

(mean for diet A) $^2 \times$  number of cows on diet A

+ (mean for diet B) $^2$  × number of cows on diet B

+ (mean for diet C) $^2$  × number of cows on diet C

so the sum of squares of residuals can be calculated simply as

sum of squares of data – sum of squares of fits.

## Sums of squares: II

Number of data	11
Number of fitted parameters	3
Difference	8

Theory predicts that the sum of squares of residuals is a random variable with mean  $8\sigma^2$ .

## Sums of squares: II

Number of data	11
Number of fitted parameters	3
Difference	8

Theory predicts that the sum of squares of residuals is a random variable with mean  $8\sigma^2$ .

So we can estimate  $\sigma^2$  by

$$\frac{\text{sum of squares of residuals}}{8}$$

This is called the residual mean square.

## Null and alternative hypotheses

Model: yield on cow 
$$i = \begin{cases} K_A + \varepsilon_i & \text{if on diet A} \\ K_B + \varepsilon_i & \text{if on diet B} \\ K_C + \varepsilon_i & \text{if on diet C} \end{cases}$$

## Null and alternative hypotheses

Model: yield on cow 
$$i = \begin{cases} K_A + \varepsilon_i & \text{if on diet A} \\ K_B + \varepsilon_i & \text{if on diet B} \\ K_C + \varepsilon_i & \text{if on diet C} \end{cases}$$

$$K_A = K_B = K_C$$
  
there is no difference  
between the diets

 $K_A = K_B = K_C$   $K_A$ ,  $K_B$  and  $K_C$  are not all the same

## Null and alternative hypotheses

Model: yield on cow 
$$i = \begin{cases} K_A + \varepsilon_i & \text{if on diet A} \\ K_B + \varepsilon_i & \text{if on diet B} \\ K_C + \varepsilon_i & \text{if on diet C} \end{cases}$$

 $K_A = K_B = K_C$ there is no difference between the diets

 $K_A = K_B = K_C$   $K_A$ ,  $K_B$  and  $K_C$  are not all the same

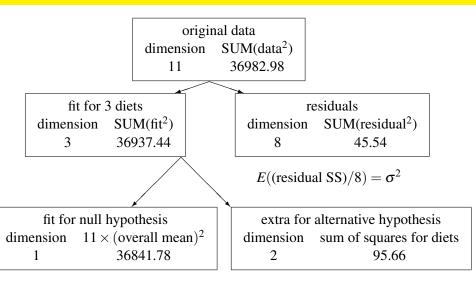

null hypothesis

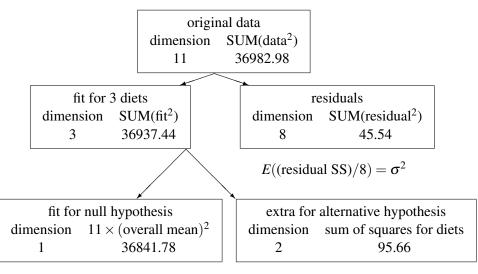

alternative hypothesis

original data dimension SUM(data²) 11 36982.98

If the null hypothesis is true,  $E((\text{diets SS})/2) = \sigma^2$

residual	8	45.54	5.69	
Total	11	36982.98	•	

If the null hypothesis is true then the two mean squares should be about the same size. Are they?

Find their ratio!

Source	Dimension	Sum of squares	Mean square	Ratio	P
null	1	36841.78			
diets	2	95.66	47.83	8.40	0.01
residual	8	45.54	5.69		
Total	11	36982.98	-		

If the null hypothesis is true then the two mean squares should be about the same size. Are they?

#### Find their ratio!

If the null hypothesis is true and the data are normal then this ratio should have an F distribution with 2 and 8 degrees of freedom (sometimes written  $F_8^2$ ). Then the probability that the ratio is 8.40 or higher is approximately 0.01 (I looked this up in statistical tables).

Source	Dimension	Sum of squares	Mean square	Ratio	P
null	1	36841.78			
diets	2	95.66	47.83	8.40	0.01
residual	8	45.54	5.68

#### End of Part I

Any questions?

## An experiment about protecting metal

An experiment was conducted to compare two protective dyes for metal, both with each other and with 'no dye'. Ten braided metal cords were broken into three pieces. The three pieces of each cord were randomly allocated to the three treatments. After the dyes had been applied, the cords were left to weather for a fixed time, then their strengths were measured, and recorded as a percentage of the nominal strength specification.

### **Assumptions**

Assumption: strength depends additively on dye and cord.

Model:

strength of piece of cord *i* with dye 
$$j = a_i + b_j + \varepsilon_{ij}$$

for 
$$i = 1, ..., 10$$
 and  $j = 1, ..., 3$ ,

where  $\varepsilon_{1,1}, \ldots, \varepsilon_{10,3}$  are independent (normal) random variables with mean zero and variance  $\sigma^2$ .

### **Assumptions**

Assumption: strength depends additively on dye and cord.

Model:

strength of piece of cord *i* with dye 
$$j = a_i + b_j + \varepsilon_{ij}$$

for i = 1, ..., 10 and j = 1, ..., 3,

where  $\varepsilon_{1,1}, \ldots, \varepsilon_{10,3}$  are independent (normal) random variables with mean zero and variance  $\sigma^2$ .

I want to find out if  $b_1$ ,  $b_2$  and  $b_3$  are different, and to estimate them. I suspect that  $a_1, \ldots, a_{10}$  are different but I do not really care.

Model: strength of piece of cord i with dye  $j = a_i + b_j + \varepsilon_{ij}$  for i = 1, ..., 10 and j = 1, ..., 3.

Model: strength of piece of cord i with dye  $j = a_i + b_j + \varepsilon_{ij}$  for i = 1, ..., 10 and j = 1, ..., 3.

Submodel: strength of piece of cord i with dye  $j = a_i + \varepsilon_{ij}$  for i = 1, ..., 10 and j = 1, ..., 3.

Model: strength of piece of cord i with dye  $j = a_i + b_j + \varepsilon_{ij}$  for i = 1, ..., 10 and j = 1, ..., 3.

Submodel: strength of piece of cord i with dye  $j = a_i + \varepsilon_{ij}$  for i = 1, ..., 10 and j = 1, ..., 3.

The submodel is a *special case* of the first model.

Model: strength of piece of cord i with dye  $j = a_i + b_j + \varepsilon_{ij}$  for i = 1, ..., 10 and j = 1, ..., 3.

Submodel: strength of piece of cord i with dye  $j = a_i + \varepsilon_{ij}$ 

for 
$$i = 1, ..., 10$$
 and  $j = 1, ..., 3$ .

The submodel is a *special case* of the first model.

Null hypothesis: the submodel is true.

Alternative hypothesis: the first model is true but the submodel is not.

Model: strength of piece of cord i with dye  $j = a_i + b_j + \varepsilon_{ij}$ Submodel: strength of piece of cord i with dye  $j = a_i + \varepsilon_{ij}$ for i = 1, ..., 10 and j = 1, ..., 3.

Model: strength of piece of cord i with dye  $j = a_i + b_j + \varepsilon_{ij}$ Submodel: strength of piece of cord i with dye  $j = a_i + \varepsilon_{ij}$ for i = 1, ..., 10 and j = 1, ..., 3.

In the submodel, the fit for piece of cord i with dye j = average of cord i.

Dimension of the submodel = 10.

Model: strength of piece of cord i with dye  $j = a_i + b_j + \varepsilon_{ij}$ Submodel: strength of piece of cord i with dye  $j = a_i + \varepsilon_{ij}$ for i = 1, ..., 10 and j = 1, ..., 3.

In the submodel, the fit for piece of cord i with dye j = average of cord i.

Dimension of the submodel = 10.

In the first model, the fit for piece of cord i with dye j = average of cord i + average of dye j – overall average

Warning: this simple method does not work unless each dye occurs on each cord equally often.

Model: strength of piece of cord i with dye  $j = a_i + b_j + \varepsilon_{ij}$ Submodel: strength of piece of cord i with dye  $j = a_i + \varepsilon_{ij}$ for i = 1, ..., 10 and j = 1, ..., 3.

In the submodel, the fit for piece of cord i with dye j = average of cord i.

Dimension of the submodel = 10.

In the first model, the fit for piece of cord i with dye j = average of cord i + average of dye j – overall average

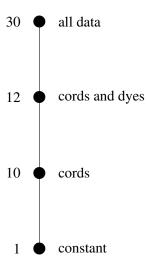

Warning: this simple method does not work unless each dye occurs on each cord equally often.

Dimension of first model = 
$$10 + 3 - 1 = 12$$

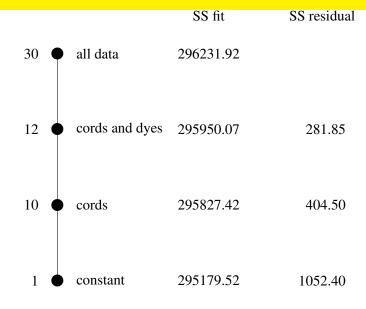

because 
$$a_i + b_j = (a_i + 1) + (b_j - 1)$$
.

They were unable to reject the hypothesis of no difference between the dyes.

### An intermediate model: to dye or not to dye

Model: strength of piece of cord i with dye  $j = a_i + b_j + \varepsilon_{ij}$ 

Submodel: strength of piece of cord i with dye  $j = a_i + \varepsilon_{ij}$ 

#### An intermediate model: to dye or not to dye

Model: strength of piece of cord i with dye  $j = a_i + b_j + \varepsilon_{ij}$ Intermediate model: strength of piece of cord i with dye  $j = \begin{cases} a_i + \varepsilon_{ij} & \text{if dye } j \text{ is 'no dye'} \\ a_i + d + \varepsilon_{ij} & \text{if dye } j \text{ is a real dye} \end{cases}$ 

Submodel: strength of piece of cord i with dye  $j = a_i + \varepsilon_{ij}$ 

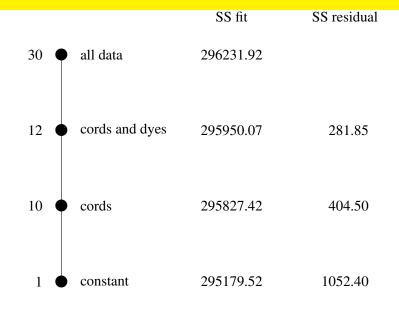

#### An intermediate model: to dye or not to dye

Model: strength of piece of cord i with dye  $j = a_i + b_j + \varepsilon_{ij}$ Intermediate model: strength of piece of cord i with dye  $j = \begin{cases} a_i + \varepsilon_{ij} & \text{if dye } j \text{ is 'no dye'} \\ a_i + d + \varepsilon_{ij} & \text{if dye } j \text{ is a real dye} \end{cases}$ 

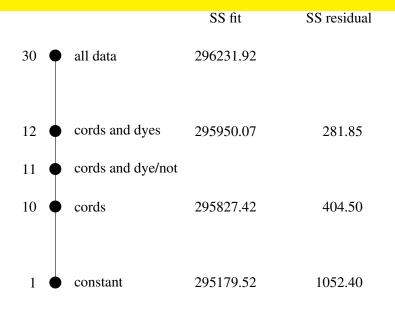

Submodel: strength of piece of cord i with dye  $j = a_i + \varepsilon_{ij}$ 

The submodel is a special case of the intermediate model, and the intermediate model is a special case of the first model.

### Better analysis of variance for dye experiment: I

Source	df	Sum of squares	Mean square	Ratio	P
cords	9	647.90			
dye/not	1	95.51	95.51	6.10	0.0238
real dyes	1	27.14	27.14	1.73	0.2049
residual	18	281.85	15.66		
Total	29	1052.40	-		

### Better analysis of variance for dye experiment: I

Source	df	Sum of squares	Mean square	Ratio	P
cords	9	647.90			
dye/not	1	95.51	95.51	6.10	0.0238
real dyes	1	27.14	27.14	1.73	0.2049
residual	18	281.85	15.66		
Total	29	1052.40	-		

First we compare the full model with the intermediate model. At the 5% level of significance we cannot reject the hypothesis that there is no difference between the two real dyes. So we simplify our assumption to the intermediate model.

### Better analysis of variance for dye experiment: I

Source	df	Sum of squares	Mean square	Ratio	P
cords	9	647.90			
dye/not	1	95.51	95.51	6.10	0.0238
real dyes	1	27.14	27.14	1.73	0.2049
residual	18	281.85	15.66		
Total	29	1052.40	-		

First we compare the full model with the intermediate model. At the 5% level of significance we cannot reject the hypothesis that there is no difference between the two real dyes. So we simplify our assumption to the intermediate model.

Then we compare the intermediate model to the submodel. At the 5% level of significance we can reject the hypothesis that 'no dye' has the same effect as real dye. We conclude that applying dyes does affect metal strength. We cannot simplify our assumption to the submodel.

An experiment on forage crops compared five seed mixtures in the presence and absence of nitrogen fertilizer. All ten combinations were grown in plots in five different fields. For each crop mixture in each field, the recorded response is improvement in yield, in tons per acre, if fertilizer is added.

Fields are like cords: we do not care about their differences.

Crop mixtures are like diets or dyes: we are interested in their differences.

Crop mixtures are not like diets and dyes, because the levels are quantitative:

100% oats 75% oats 50% oats 25% oats 0% oats 0% vetch 25% vetch 50% vetch 75% vetch 100% vetch

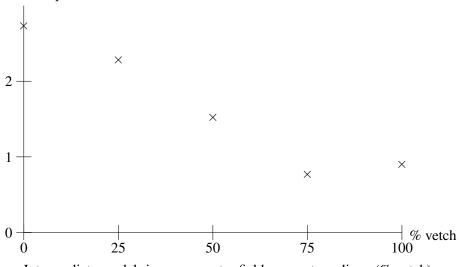

#### An intermediate model: linear in vetch

mean improvement with N, in tons/acre

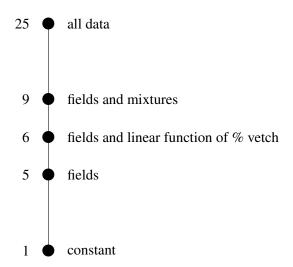

#### An intermediate model: linear in vetch

mean improvement with N, in tons/acre

Intermediate model: improvement = field parameter + linear(% vetch)

## Diagram of models

## Another warning about practice

In the forage crops example, almost all the differences between the mixtures can be explained as a linear function of the percentage of vetch.

Source	df	Sum of squares	Mean square	Ratio
fields				
linear in vetch	1	0.2663	0.2663	6.62
mixtures	3	0.0254	0.0085	0.21
residual			0.0402	

## Another warning about practice

In the forage crops example, almost all the differences between the mixtures can be explained as a linear function of the percentage of vetch.

Source	df	Sum of squares	Mean square	Ratio
fields				
linear in vetch	1	0.2663	0.2663	6.62
mixtures	3	0.0254	0.0085	0.21
residual			0.0402	

The first statistician who analysed these data did it in the simple way:

Source	df	Sum of squares	Mean square	Ratio
fields				
mixtures	4	0.2917	0.0729	1.81
residual			0.0402	

and concluded that there was not enough evidence that the mixtures had different effects.

#### Polynomial models

Suppose that we measure quantities  $x_i$  and  $y_i$  on item i, for i = 1, ..., n.

We want a model that predicts y as a function of x. We might try a cubic polynomial:

$$y_i = a + bx_i + cx_i^2 + dx_i^3 + \varepsilon_i.$$

#### Polynomial models

Suppose that we measure quantities  $x_i$  and  $y_i$  on item i, for i = 1, ..., n.

We want a model that predicts y as a function of x. We might try a cubic polynomial:

$$y_i = a + bx_i + cx_i^2 + dx_i^3 + \varepsilon_i.$$

A special case is the quadratic polynomial:

$$y_i = e + fx_i + gx_i^2 + \varepsilon_i,$$

### Polynomial models

Suppose that we measure quantities  $x_i$  and  $y_i$  on item i, for i = 1, ..., n.

We want a model that predicts y as a function of x. We might try a cubic polynomial:

$$y_i = a + bx_i + cx_i^2 + dx_i^3 + \varepsilon_i.$$

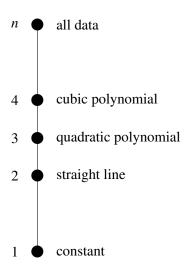

A special case is the quadratic polynomial:

$$y_i = e + fx_i + gx_i^2 + \varepsilon_i,$$

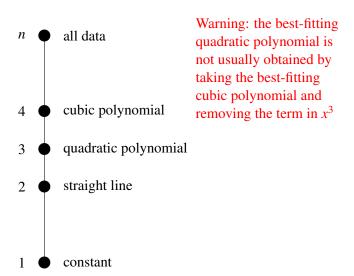

and a special case of that is the straight line:

$$y_i = h + kx_i + \varepsilon_i$$
.

residual	4	529.0	132.25		
Total	7	8482.0	-		

## Anova for chick-feeding experiment: I

Source	df	Sum of squares	Mean square	Ratio	P
protein	1	4704.5	4704.50	35.57	0.004
fishmeal	1	3120.5	3120.50	23.60	0.0083
diets	1	128.0	128.00	0.97	0.3804
residual	4	529.0	132.25		
Total	7	8482.0	=		

First we compare the full model with the additive model. At the 5% level of significance we cannot reject the hypothesis that the additive model is true.

This means that the difference caused by adding fishmeal is the same for both proteins. We say that "fishmeal does not interact with protein" or "there is no interaction between the two factors". So we simplify our assumption to the additive model.

# Anova for chick-feeding experiment: II

Source	df	Sum of squares	Mean square	Ratio	P
protein	1	4704.5	4704.50	35.57	0.004
