

# Optimal design of experiments with very low average replication

R. A. Bailey

`r.a.bailey@qmul.ac.uk`

Piracicaba, May 2012

# Abstract

Trials of new crop varieties usually have very low average replication.

# Abstract

Trials of new crop varieties usually have very low average replication. Thus one possibility is to have a single plot for each new variety and several plots for a control variety, with the latter well spread out over the field.

# Abstract

Trials of new crop varieties usually have very low average replication. Thus one possibility is to have a single plot for each new variety and several plots for a control variety, with the latter well spread out over the field. A more recent proposal is to ignore the control, and instead have two plots for each of a small proportion of the new varieties.

# Abstract

Trials of new crop varieties usually have very low average replication. Thus one possibility is to have a single plot for each new variety and several plots for a control variety, with the latter well spread out over the field. A more recent proposal is to ignore the control, and instead have two plots for each of a small proportion of the new varieties.

Variation in the field may be accounted for by a polynomial trend, by spatial correlation, or by blocking.

# Abstract

Trials of new crop varieties usually have very low average replication. Thus one possibility is to have a single plot for each new variety and several plots for a control variety, with the latter well spread out over the field. A more recent proposal is to ignore the control, and instead have two plots for each of a small proportion of the new varieties.

Variation in the field may be accounted for by a polynomial trend, by spatial correlation, or by blocking. However, if the experiment has a second phase, such as making bread from flour milled from the grain produced in the first phase, then that second phase usually has blocks.

# Abstract

Trials of new crop varieties usually have very low average replication. Thus one possibility is to have a single plot for each new variety and several plots for a control variety, with the latter well spread out over the field. A more recent proposal is to ignore the control, and instead have two plots for each of a small proportion of the new varieties.

Variation in the field may be accounted for by a polynomial trend, by spatial correlation, or by blocking. However, if the experiment has a second phase, such as making bread from flour milled from the grain produced in the first phase, then that second phase usually has blocks.

The optimality criterion used is usually the A criterion: the average variance of the pairwise differences between the new varieties.

# Abstract

Trials of new crop varieties usually have very low average replication. Thus one possibility is to have a single plot for each new variety and several plots for a control variety, with the latter well spread out over the field. A more recent proposal is to ignore the control, and instead have two plots for each of a small proportion of the new varieties.

Variation in the field may be accounted for by a polynomial trend, by spatial correlation, or by blocking. However, if the experiment has a second phase, such as making bread from flour milled from the grain produced in the first phase, then that second phase usually has blocks.

The optimality criterion used is usually the A criterion: the average variance of the pairwise differences between the new varieties.

I shall compare designs under the A criterion when the average replication is much less than two.

# Agricultural plant-breeding trials

In breeding trials of new varieties, typically there is very little seed of each of the new varieties.

## Example

There are 224 new varieties, with very little seed of each.

# Agricultural plant-breeding trials

In breeding trials of new varieties, typically there is very little seed of each of the new varieties.

## Example

There are 224 new varieties, with very little seed of each.

There are 280 plots available, in a  $14 \times 20$  rectangle.

# Agricultural plant-breeding trials

In breeding trials of new varieties, typically there is very little seed of each of the new varieties.

## Example

There are 224 new varieties, with very little seed of each.

There are 280 plots available, in a  $14 \times 20$  rectangle.

How do you design the experiment?

# Agricultural plant-breeding trials

In breeding trials of new varieties, typically there is very little seed of each of the new varieties.

## Example

There are 224 new varieties, with very little seed of each.

There are 280 plots available, in a  $14 \times 20$  rectangle.

How do you design the experiment?

Assume that

number of varieties  $<$  number of plots

and

number of plots  $\ll 2 \times$  (number of varieties).

## Some notation

$f(\omega)$  = variety on plot  $\omega$ .

## Some notation

$f(\omega)$  = variety on plot  $\omega$ .

$Y_\omega$  = response on plot  $\omega$ .

## Some notation

$f(\omega)$  = variety on plot  $\omega$ .

$Y_\omega$  = response on plot  $\omega$ .

$\tau_i$  = effect of variety  $i$ .

## Some notation

$f(\omega)$  = variety on plot  $\omega$ .

$Y_\omega$  = response on plot  $\omega$ .

$\tau_i$  = effect of variety  $i$ .

Assume that

$$Y_\omega = \tau_{f(\omega)} + \text{stuff depending on plots.}$$

## Some notation

$f(\omega)$  = variety on plot  $\omega$ .

$Y_\omega$  = response on plot  $\omega$ .

$\tau_i$  = effect of variety  $i$ .

Assume that

$$Y_\omega = \tau_{f(\omega)} + \text{stuff depending on plots.}$$

We want to minimize

$$\sum_i \sum_{j \neq i} \text{Var}(\hat{\tau}_i - \hat{\tau}_j).$$

# Simplest model

$$Y_{\omega} = \tau_{f(\omega)} + \epsilon_{\omega}$$

where

$$\begin{aligned} E(\epsilon_{\omega}) &= 0, & \text{Var}(\epsilon_{\omega}) &= \sigma^2, \\ \text{and } \text{Cov}(\epsilon_{\omega}, \epsilon_{\omega'}) &= 0 \quad \text{if } \omega \neq \omega'. \end{aligned}$$

# Simplest model

$$Y_{\omega} = \tau_{f(\omega)} + \epsilon_{\omega}$$

where

$$E(\epsilon_{\omega} = 0), \quad \text{Var}(\epsilon_{\omega}) = \sigma^2,$$

$$\text{and } \text{Cov}(\epsilon_{\omega}, \epsilon_{\omega'}) = 0 \text{ if } \omega \neq \omega'.$$

The A-optimal design has

2 plots for some varieties and 1 plot for all other varieties,  
and is completely randomized.

## Simplest model: example

56 varieties have replication 2;  
168 varieties have replication 1.

## Simplest model: example

56 varieties have replication 2;  
168 varieties have replication 1.

[illegible]

## Simplest model: example

56 varieties have replication 2;  
168 varieties have replication 1.

[illegible]

## Simplest model: example

56 varieties have replication 2;  
168 varieties have replication 1.

[illegible]

A breeder says . . .

Unfair!

The single plot with my variety was in an infertile part of the field.

## Fixed spatial trend

$$Y_{\omega} = \tau_{f(\omega)} + g(\omega) + \epsilon_{\omega}$$

where

$g(\omega)$  is a two-dimensional low-degree polynomial in  $\omega$ ,

$$E(\epsilon_{\omega}) = 0, \quad \text{Var}(\epsilon_{\omega}) = \sigma^2,$$

and  $\text{Cov}(\epsilon_{\omega}, \epsilon_{\omega'}) = 0$  if  $\omega \neq \omega'$ .

## Fixed spatial trend

$$Y_{\omega} = \tau_{f(\omega)} + g(\omega) + \epsilon_{\omega}$$

where

$g(\omega)$  is a two-dimensional low-degree polynomial in  $\omega$ ,

$$E(\epsilon_{\omega} = 0), \quad \text{Var}(\epsilon_{\omega}) = \sigma^2,$$

$$\text{and } \text{Cov}(\epsilon_{\omega}, \epsilon_{\omega'}) = 0 \text{ if } \omega \neq \omega'.$$

Caliński, Mejza, ...:

## Fixed spatial trend

$$Y_{\omega} = \tau_{f(\omega)} + g(\omega) + \epsilon_{\omega}$$

where

$g(\omega)$  is a two-dimensional low-degree polynomial in  $\omega$ ,

$$E(\epsilon_{\omega} = 0), \quad \text{Var}(\epsilon_{\omega}) = \sigma^2,$$

$$\text{and } \text{Cov}(\epsilon_{\omega}, \epsilon_{\omega'}) = 0 \text{ if } \omega \neq \omega'.$$

Caliński, Mejza, ...:

use one plot for each new variety

## Fixed spatial trend

$$Y_{\omega} = \tau_{f(\omega)} + g(\omega) + \epsilon_{\omega}$$

where

$g(\omega)$  is a two-dimensional low-degree polynomial in  $\omega$ ,

$$E(\epsilon_{\omega} = 0), \quad \text{Var}(\epsilon_{\omega}) = \sigma^2,$$

$$\text{and } \text{Cov}(\epsilon_{\omega}, \epsilon_{\omega'}) = 0 \text{ if } \omega \neq \omega'.$$

Caliński, Mejza, ...:

use one plot for each new variety

and several plots for a well-established but uninteresting  
“control”;

## Fixed spatial trend

$$Y_{\omega} = \tau_{f(\omega)} + g(\omega) + \epsilon_{\omega}$$

where

$g(\omega)$  is a two-dimensional low-degree polynomial in  $\omega$ ,

$$E(\epsilon_{\omega} = 0), \quad \text{Var}(\epsilon_{\omega}) = \sigma^2,$$

$$\text{and } \text{Cov}(\epsilon_{\omega}, \epsilon_{\omega'}) = 0 \text{ if } \omega \neq \omega'.$$

Caliński, Mejza, ...:

use one plot for each new variety

and several plots for a well-established but uninteresting  
“control”;

place the “control” plots in a grid;

# Fixed spatial trend

$$Y_{\omega} = \tau_{f(\omega)} + g(\omega) + \epsilon_{\omega}$$

where

$g(\omega)$  is a two-dimensional low-degree polynomial in  $\omega$ ,

$$E(\epsilon_{\omega} = 0), \quad \text{Var}(\epsilon_{\omega}) = \sigma^2,$$

		X				X				X	1				X		
		X				X				X					X		
		X				X				X					X		
		X				X				X					X		
		X				X				X					X		

Controls are on every fifth plot, working along rows.

## Spatial trend: example, another layout

56 plots for “control”

224 new varieties have replication 1.

## Spatial trend: example, another layout

56 plots for “control”

224 new varieties have replication 1.

	X						X			X						X	
				X	X								X	X			
X								X	X								X
			X			X						X				X	
		X					X					X					X
	X						X			X							X
				X	X								X	X			
X								X	X								X
			X			X							X			X	
		X					X					X					X
	X						X			X							X
				X	X								X	X			
X								X	X								X
			X			X							X			X	

Controls are on every 5th plot, working boustrophedon along columns.

## Spatial trend: example, a third layout

56 plots for “control”

224 new varieties have replication 1.

## Spatial trend: example, a third layout

56 plots for “control”

224 new varieties have replication 1.

X	X		X	X		X	X		X	X	
X	X		X	X		X	X		X	X	
X	X		X	X		X	X		X	X	
X	X		X	X		X	X		X	X	
X	X		X	X		X	X		X	X	
X	X		X	X		X	X		X	X	

Controls are on a complete sub-rectangle

## Spatial trend: example, what should we optimize?

56 plots for “control”

224 new varieties have replication 1.

# Spatial trend: example, what should we optimize?

56 plots for “control”

224 new varieties have replication 1.

X	X					X	X								X	X					X	X
X	X					X	X								X	X					X	X
X	X																				X	X
X	X					X									X						X	X
										X	X											
										X	X											
X	X					X									X						X	X
X	X																				X	X
X	X					X	X								X	X					X	X
X	X					X	X								X	X					X	X

Controls are positioned to make the **average** variance of prediction small if the trend is a polynomial of degree **three**.

## Spatial trend: example, what should we optimize/assume?

56 plots for “control”

224 new varieties have replication 1.

# Spatial trend: example, what should we optimize/assume?

56 plots for “control”

224 new varieties have replication 1.

X	X	X						X	X	X	X							X	X	X
X	X	X																X	X	X
X																				X
X																				X
X									X	X										X
X									X	X										X
X									X	X										X
X									X	X										X
X																				X
X																				X
X	X	X																X	X	X
X	X	X						X	X	X	X							X	X	X

Controls are positioned to make the **maximum** variance of prediction small if the trend is a polynomial of degree **two**.

Yates (1936), Atiqullah and Cox (1962) consider controls spread throughout the field. In their analysis, a weighted mean of the response on the nearest controls is used as a covariate, rather than being simply subtracted.

# Spatial correlation

where

$$Y_{\omega} = \tau_{f(\omega)} + \epsilon_{\omega}$$

and

$$E(\epsilon_{\omega} = 0), \quad \text{Var}(\epsilon_{\omega}) = \sigma^2,$$

$\text{Cov}(\epsilon_{\omega}, \epsilon_{\omega'})$  depends on the spatial relationship between  $\omega$  and  $\omega'$ .

# Spatial correlation

## Blocks: example

Rows are blocks, so there are 14 blocks, each with 20 plots.

## Blocks: example, continued

224 varieties in 14 blocks of size 20.

## Blocks: example, continued

224 varieties in 14 blocks of size 20.

( $280 - 224 = 56$  and  $224 - 56 = 168$ ,

so at least 168 varieties must have single replication.)

## Blocks: example, continued

224 varieties in 14 blocks of size 20.

( $280 - 224 = 56$  and  $224 - 56 = 168$ ,

so at least 168 varieties must have single replication.)

14 blocks	{	8 plots		12 plots	whole design $\Delta$
		$\vdots$		$\vdots$	
		56 varieties		168 varieties all single replication	

Subdesign  $\Gamma$  has 56 varieties  
in 14 blocks of size 8.

## Blocks: remember that replication is very low

Yates (1936) concluded that square-lattice incomplete-block designs are superior to the inclusion of controls, but all of his examples had average replication equal to three or more.

## Blocks: remember that replication is very low

Yates (1936) concluded that square-lattice incomplete-block designs are superior to the inclusion of controls, but all of his examples had average replication equal to three or more.

Here we assume that average replication is (much) less than two.

# A general block design with average replication less than 2

# A general block design with average replication less than 2

Whole design  $\Delta$  has  $v + bn$  varieties in  $b$  blocks of size  $k + n$ ;

# A general block design with average replication less than 2

Whole design  $\Delta$  has  $v + bn$  varieties in  $b$  blocks of size  $k + n$ ;  
 the subdesign  $\Gamma$  has  $v$  **core** varieties in  $b$  blocks of size  $k$ ;

# A general block design with average replication less than 2

Whole design  $\Delta$  has  $v + bn$  varieties in  $b$  blocks of size  $k + n$ ;  
the subdesign  $\Gamma$  has  $v$  **core** varieties in  $b$  blocks of size  $k$ ;  
call the remaining varieties **orphans**.

# Pairwise variance: two orphans in the same block

$b$ blocks	{	$k$ plots		$n$ plots	whole design $\Delta$

# Sum of the pairwise variances

Theorem (cf Herzberg and Jarrett, 2007)

*The sum of the variances of treatment differences in  $\Delta$*

$$= \text{constant} + V_1 + nV_3 + n^2V_2,$$

*where*

$V_1$  = *the sum of the variances of treatment differences in  $\Gamma$*

$V_2$  = *the sum of the variances of block differences in  $\Gamma$*

$V_3$  = *the sum of the variances of sums of  
one treatment and one block in  $\Gamma$ .*

(If  $\Gamma$  is equi-replicate then  $V_2$  and  $V_3$  are both increasing functions of  $V_1$ .)

# Sum of the pairwise variances

Theorem (cf Herzberg and Jarrett, 2007)

*The sum of the variances of treatment differences in  $\Delta$*

$$= \text{constant} + V_1 + nV_3 + n^2V_2,$$

*where*

$V_1$  = *the sum of the variances of treatment differences in  $\Gamma$*

$V_2$  = *the sum of the variances of block differences in  $\Gamma$*

$V_3$  = *the sum of the variances of sums of  
one treatment and one block in  $\Gamma$ .*

(If  $\Gamma$  is equi-replicate then  $V_2$  and  $V_3$  are both increasing functions of  $V_1$ .)

Consequence

For a given choice of  $k$ , make  $\Gamma$  as efficient as possible.

# A less obvious consequence

## Consequence

If  $n$  or  $b$  is large,  
it may be best to make  $\Gamma$  a complete block design for  $k'$  controls,  
even if there is no interest in comparisons between new  
treatments and controls, or between controls.

## $5n + 10$ treatments in 5 blocks of size $4 + n$

1	2	3	4	$A_1$	$\cdots$	$A_n$
3	4	5	6	$B_1$	$\cdots$	$B_n$
5	6	7	8	$C_1$	$\cdots$	$C_n$
7	8	9	0	$D_1$	$\cdots$	$D_n$
9	0	1	2	$E_1$	$\cdots$	$E_n$

Youden and Connor (1953):  
“experiments in physics do not need much replication because results are not very variable” —introduced chain block designs

## $5n + 10$ treatments in 5 blocks of size $4 + n$

1	2	3	4	$A_1$	$\cdots$	$A_n$
